Abstract

Tool sequence selection is an important task for 2.5D pocket milling and has a significant influence on both the energy consumption and machining cost of the final product. In this paper, the influence of tool sequence on energy consumption is firstly analyzed. Then a multi-objective tool sequence optimization model is proposed with the objective of minimizing energy consumption and machining cost and solved by the graph algorithm. Finally, a case study is carried out to validate the proposed model and search for the trade-off solutions between energy consumption and machining cost.

Keywords: Tool sequence optimization; Energy consumption; CNC milling; 2.5D pocket

1. Introduction

In 2013, the energy consumption of industrial sector accounts for 30% of the total energy used in the United States [1]. In the case of China, it makes a large contribution to overall energy consumption of over 60% of the total [2]. Thus, reducing energy consumption of industrial sector is identified as a priority area due to the global increasing imbalance between energy supply and demand. In fact, CNC machining is a widely used subtractive process in the industrial sector, which is responsible for a substantial portion of the total industry consumed energy. Reducing the energy consumption of CNC machining processes can account for significant decrement of the environmental impact.

In recent years, many researchers have studied the issue to characterize energy consumption of machine tools. Gutowski et al. differentiated the energy requirements for a wide range of machining processes into a constant and a variable portion. The fixed power comes from the basic equipment required to support the accomplishment of the machining tasks; while the variable portion is dependent on the rate of material processing [3]. Based on the work of Gutowski et al., Li et al. explored the breakdown of fixed energy consumption of machine tools into auxiliary, cooling hydraulic, lubrication, and other power units. Six machine tools covering different machining processes are selected for this investigation in order to evaluate the future energy savings [4]. In the work presented by Balogun and Mativenga, the direct energy requirements of general mechanical machining processes were also studied [5]. A comprehensive overview of such models can be found in [6].

Based on the above researches, efforts related to the energy reduction of machining processes have been made in the perspectives of cutting parameters optimization and process planning optimization. For instance, Velchev et al. proposed a model to minimize energy consumption with respect to insert grade, feed rate and cutting depth [7]. Rajemi et al. modelled and optimized the energy of a turning process in order to derive an economic tool-life and cutting parameters that satisfied the minimum energy footprint requirement [8]. Similarly, Valera and Bhavsar explored the effect of cutting parameters on surface roughness and power consumption in turning operation. The experiments found that increase in spindle speed improves surface finish at the cost of power consumption, while increase in feed rate or depth of cut multiplies both roughness and power consumption [9]. Apart from the researches related to the parameter optimization for energy consumption reduction, many studies focused on the
optimization of the machining process planning. Newman et al. pointed out that energy consumption of interchangeable machining processes can differ significantly, by at least 6% of the total in low loads and is likely to up to 40% at higher loads [10]. The work presented by Zhang et al. shows that the machining features of the workpiece are used to automatically or semi-automatically generate feasible process plans with energy consumption consideration [11]. Other relevant works can be found in [12].

CNC milling is a widely used processing method that removes metal by a rotating multiple tooth cutter. Milling using a set of cutting tools has become very attractive with machining efficiency and cost considerations. Thus, the cutting tool sequence selection is an important activity in process-planning for milling. In recent years, many researchers have studied the challenges associated with tool sequence selection. D’Souza et al. described a valid method based on the Directed graph to find an optimal tool sequence for the lowest machining cost in 2.5D and 3D pockets rough machining [13-14]. Chen et al. presented a toolpath generation approach based on the medial axis transform and proposed an optimization model of selecting multiple tools with the aim of minimizing production time in 2.5D pocket rough milling [15]. Geng et al. developed a toolpath length estimation approach to determine an optimal tool sequence in sculptured surfaces milling for maximizing the machining efficiency [16]. Yao et al. have formulated a multipart milling problem using the geometric algorithms to select an optimal tool sequence for reducing the machining time in several distinct 2.5D pockets milling [17]. Other relevant work on optimization of tool sequence can be found in [18-19].

A perusal of current literature concludes that existing research about tool sequence optimization in 2.5D pocket milling is only concentrated on reduction of machining time and cost. While significant efforts have been devoted to analyse energy consumption of machine tools, little of them looked into tool sequence optimization. However, the energy consumption of the milling process is highly dependent on the tool diameter as the machining power and time vary with it [20]. Thus, optimizing tool sequence can effectively reduce the energy consumption in CNC milling process.

Given the lack of work in optimizing the tool sequence considering energy consumption reduction, this paper fills this gap and studies multi-objective tool sequence optimization with the aim of minimizing energy consumption and machining cost for 2.5 D pocket CNC milling. The rest of the paper is organized as follows. Section 2 is the statement of the optimization problem. Section 3 analyses the influence of tool sequence on energy consumption. In Section 4, a multi-objective tool sequence optimization model is proposed for minimizing energy consumption and machining cost. The solution through the graph algorithm is presented in Section 5. The validity of this approach is demonstrated through a case study Section 6, followed by the conclusion and future research in Section 7.

2. Problem Statement

With the development of automatic tool changers in modern CNC milling center, it is practical to use multiple cutting tools to quickly finish the product, as large tools can rapidly generate the rough shape and a smaller clearing tool can generate the net-shape. For a given 2.5D pocket, the accessible area of each feasible tool is restricted by its internal geometry. Smaller tools have larger accessible areas inside the pocket as compared to larger ones.

The problem of optimal tool sequence selection in 2.5D pocket machining is defined as follows. Given a 2.5D pocket and there are a set of cutting feasible tools \( T_f = \{ T_1, T_2, ..., T_n \} \) with diameter \( D(T_1) > D(T_2) > ... > D(T_n) \). The critical tool \( T_{cr} \) (i.e. \( T_1 \)) is the only one feasible tool which is small enough to machine the pocket completely without gouging; hence each tool sequence contains the cutter \( T_{cr} \). The problem is to find an optimal tool sequence \( T = \{ T_1, T_2, ..., T_n \} \) to produce the 2.5D pocket with the goal of incurring the minimum combined energy consumption and cost, and the cutters will be used in descending order of sizes.

3. Tool sequence influence on energy consumption of the 2.5D pocket CNC milling

3.1. Composition of energy consumption in CNC milling

The energy consumption of a milling operation can be calculated as shown in Eq.(1):

\[
E = E_0 + E_u + E_c + E_a
\]

(1)

Where \( E_0 \) is the fixed energy consumed by the machine modules, \( E_u \) is the unload energy to keep the spindle rotating, \( E_c \) is the cutting energy to remove the workpiece material and \( E_a \) is the additional load loss energy generated by cutting load [21].

According to the work presented in [21], the energy consumption of the machine tool can be calculated as:

\[
E = E_0 + E_u + E_c + E_a = P_0(t_{air} + t_c) + P_a(t_{air} + t_c) + P_c t_c + P_a t_c
\]

(2)

Where \( P_0 \) is the fixed power consumed by the activated machine components that ensure the operational readiness of the machine tool, such as lighting and coolant pump. \( P_c \) is the unload power when spindle runs steadily without material removal. \( P_c \) is the cutting power consumed at the tool tip for removing workpiece material. \( P_a \) is the additional load loss power generated by cutting force, which is a linear function in terms of the cutting power \( P_c \), i.e. \( P_a = b_a P_c \). Where \( b_a \) is the correlation coefficient. \( t_{air} \) is the air cutting time without removing material. \( t_c \) is the cutting time to remove the workpiece material.

When machining the 2.5D pocket, there may be many feasible milling strategies with different tool sequences. The accessible area of each feasible tool varies with the pocket internal geometry and the tool sequence. From Eq. (2), it can be found that the energy consumption for each feasible tool sequence varies with the unload power \( P_u \), cutting power \( P_c \), air cutting time \( t_{air} \) and cutting time \( t_c \). The detailed analysis is given below.

3.2. The influence of tool diameter on unload power and cutting power

In the milling process, the cutting parameters \( p(n, f, a_p, a_n) \)
differs with the cutting tool diameter \( D(T) \). As the unload power \( P_u \) and the cutting power \( P_c \) are related to the cutting parameters \( p(n,f_a,a_x,a_y) \), the unload power \( P_u \) and the cutting power \( P_c \) will differ with the cutting tool diameter \( D(T) \).

\[
\begin{align*}
|P_c| &= f(D(T)) \\
|P_u| &= f(p(n,f_a,a_x,a_y),D(T))
\end{align*}
\]  
(3)

Where \( n, f_a, a_x \), and \( a_y \) are the spindle speed, feed rate, width of cut and depth of cut, respectively.

### 3.2.1. The influence of tool diameter on unload power

The unload power \( P_u \) is mainly consists of the power demand by motors, inverters and transmission, which is a quadratic function in terms of the spindle speed \( n \) \[21\]:

\[
P_u = P_{ua} + a_1 n + a_2 n^2
\]

\[
= P_{ua} + a_1 \frac{1000}{D(T)} + a_2 \frac{4000}{D(T)^2}
\]  
(4)

Where \( P_{ua}, a_1 \), and \( a_2 \) are unload power coefficients, \( v_c \) is cutting velocity. From Eq.(6), it can be found that the unload power \( P_u \) is dependent on the tool diameter \( D(T) \).

### 3.2.2. The influence of tool diameter on cutting power

The cutting power \( P_c \) is related to cutting force \( F_c \) and cutting velocity \( v_c \). The simplified relationship is given below \[8\]

\[
P_c = F_c \times v_c
\]  
(5)

\[
F_c = k_v \frac{a_x v_x f_x a_y v_y}{D(T)^y n^z}
\]  
(6)

\[
v_c = \frac{\pi D(T)n}{1000}
\]  
(7)

Where \( k_v, C_v, x_v, y_v, u_v, q_v, w_f \) are the corresponding exponents related to the cutter and workpiece material. From Eq.(5)-(7), it can be found that the cutting power \( P_c \) will change with the tool diameter \( D(T) \).

### 3.2.3. The influence of the accessible area on air cutting time and cutting time

Air cutting time \( t_{air} \) and cutting time \( t_c \) are dependent on the air cutting length \( l_{air} \) and cutting length \( l_c \) respectively. When machining the 2.5D pocket, the accessible area \( A_f \) of each cutting tool differs with its internal profile. Besides, the accessible area \( A_f \) of a specific cutting tool will also change with different tool sequence. Hence, the air cutting length \( l_{air} \) and cutting length \( l_c \) will be changed due to different tool sequence. For that reason, the air cutting time \( t_{air} \) and cutting time \( t_c \) will be changed. The influence of accessible area \( A_f \) on air cutting time \( t_{air} \) and cutting time \( t_c \) can be expressed as follows

\[
\begin{align*}
t_{air} &= f(l_{air}) \\
t_c &= f(l_c)
\end{align*}
\]  
(8)

3.3.1. The accessible area with different tool sequence for a specific cutting tool

Given an feasible tool set \( T_i \) with \( i = 1,2,...,n \) with diameter \( D(T) \) \( > \) \( D(T) \) \( > \) \( D(T) \) \( > \) \( D(T) \), and for any two feasible tool \( T_i \), \( T_j \) \( \ni \) \( j \) \( \ni \) \( n \) which has the accessible area \( A_f^{k} \), \( A_f^{k} \) respectively, then \( A_f^{k} \subset A_f^{k} \). In other words, smaller tools have larger accessible areas inside the pocket as compared to larger tools. Furthermore, no matter which larger tool is used before \( T_i \) as long as the \( T_i \) has done its own areas machining then the shape of the pocket is always same \[18\]. Consider a tool sequence with \( m \) feasible tools which are selected from the feasible tool set \( T_i \), let \( A_f^{k} \) \( \ni \) \( k \) \( \ni \) \( m \) and \( \Delta A_f^{k} \) represent the theoretical accessible area and the actual accessible area of the \( k \) \( \ni \) feasible tool respectively. Then the actual accessible area of the feasible tools can be expressed as follows

\[
\Delta A_f^{k} = \begin{cases} A_f^{k}, k = 1 \\ A_f^{k} - A_f^{k}, 1 < k \leq m
\end{cases}
\]  
(9)

3.3.2. The influence of the accessible area on air cutting time

The air cutting time \( t_{air} \) is related to the air cutting length \( l_{air} \) and the air cutting feed rate \( f_{air} \)

\[
t_{air} = \frac{l_{air}}{f_{air}} = \frac{l_{air-q}}{f_{air-q}} + \frac{l_{air-r}}{f_{air-r}}
\]  
(10)

Where \( l_{air-q}, l_{air-r} \) are the air cutting length of the rapid-feed movement and slowly-approach motion without material removal respectively, and \( f_{air-q}, f_{air-r} \) are the related air cutting feed rate. In the pocket machining process, the actual accessible area of a specific cutting tool is determined by the previous one in a feasible tool sequence. Hence, for a specific cutting tool, its actual accessible area \( \Delta A_f^{k} \) varies with different tool sequence. The air cutting length \( l_{air-q} \) and \( l_{air-r} \) will be changed due to the changed actual accessible area \( \Delta A_f^{k} \).

3.3.3. The influence of the accessible area on cutting time

Similar to the air cutting time, the cutting time \( t_c \) is also related with the cutting length \( l_c \) and the cutting feed rate \( f_c \). In the milling process, the Contour-Parallel strategy is usually used to generate the toolpath. Thus, the cutting time \( t_c \) can be calculated approximately as follows

\[
t_c = \frac{l_c}{f_c} = \sum_{i=1}^{N} \frac{l_i}{f_i} = \sum_{i=1}^{N} \frac{\Delta A_f^{k}}{\sum_{i=1}^{N} \Delta A_f^{k}}
\]  
(11)

Where \( N \) is the number of machining passes, \( l_i \) is the tool path length of the \( i \) \( \ni \) pass, \( \varepsilon \) is the interval factor of toolpath.

As shown in Eq.(11), the cutting time \( t_c \) is related to the tool path length \( l_i \) which is determined by the tool diameter \( D(T) \) and its actual accessible area \( \Delta A_f^{k} \).
4. Multi-objective tool sequence optimization model

4.1. Variable

As discussed above, the energy consumption of 2.5D pocket CNC milling varies with different tool sequences, thus the tool sequence is the optimization variable in this paper.

4.2. Objective functions

For the tool sequence optimization, many researchers have studied the optimization objectives of machining time or cost. In this paper, the objectives of energy consumption and machining cost are synthetically considered.

4.2.1. Energy consumption

From the analysis of section 3.3.1, suppose $S_k$ represents the pocket’s shape after the $k^{th}$ ($k=1,2,…,m$) tool has machined its accessible area. Thus, the energy demand $E_k(S_k,S_{k-1})$ of the $k^{th}$ tool $T_k$ in machining process can be obtained by

$$E_k(S_k,S_{k-1}) = E_k(S_k,S_{k-1}) + E_k(S_{k-1},S_{k-2}) + \ldots + E_k(S_1,S_0)$$

Therefore, the total energy consumption can be expressed as

$$E_{total} = \sum_{k=1}^{m} E_k(S_k,S_{k-1})$$

4.2.2. Machining Cost

The machining cost is the sum of overhead cost $C_O$, cutting tool cost $C_T$, and energy cost $C_E$; Thus, the machining cost $\Delta C_k(S_k,S_{k-1})$ of the $k^{th}$ tool $T_k$ can be generally described as

$\Delta C_k(S_k,S_{k-1}) = (C_O + C_T + C_E)_k$

Thus, the total machining cost can be expressed as

$$C_{total} = \sum_{k=1}^{m} \Delta C_k(S_k,S_{k-1})$$

4.2.2.1. Overhead cost $C_O$

Overhead cost is modelled as the production of the overhead cost per unit time $T$ and the total machining time

$$C_O = R \times (t_m + t_c)$$

4.2.2.2. Cutting tool cost $C_T$

Cutting tool cost $C_T$ is associated with cutting time and the tool life as shown in Eq.(17)

$$C_T = \frac{V_m}{u_x} \frac{(q_v + q_w)}{T_l}$$

Where $k$, $C_r$, $q_v$, $r_v$, $y_r$, $u_x$, $p_r$, $m$ are the corresponding coefficient.

4.2.2.3. Energy cost $C_E$

Energy cost $C_E$ is evaluated from the product of the energy consumption $\Delta E$ multiplied by its unit cost $C_{en}$, which can be expressed as

$$C_E = \lambda_{en} \times \Delta E$$

4.3. Multi-objective optimization model

There are two methods to solve the problem of multi-objective optimization. The first one uses an aggregation of the objectives to remain in the single-objective context. The other one is the so-called Pareto multi-objective optimization. Due to the features of simple concept, computational efficiency, and easy implementation, the first technique is adopted in this paper. The optimization objective weighted sum of energy consumption and machining cost can be expressed as

$$\Delta V_k (S_k,S_{k-1}) = w_1 E_k (S_k,S_{k-1}) + w_2 \Delta C_k (S_k,S_{k-1})$$

where $\Delta V_k$ is the optimization objective weighted sum of machining cost and energy consumption and machining cost of the feasible cutting tool $T_k$, $w_1$ and $w_2$ are the weight coefficients, $w_1 + w_2 = 1$.

With the variable and objectives defined above, the multi-objective tool sequence optimization model for minimizing energy consumption and machining cost of 2.5D pocket CNC milling is then formulated as follows

$$\min F(T^*_k) = (\min E_{total}, \min C_{total}) = \min \sum_{k=1}^{m} \Delta V_k (S_k,S_{k-1})$$

subject to $\Delta V_k (S_k,S_{k-1}) = w_1 E_k (S_k,S_{k-1}) + w_2 \Delta C_k (S_k,S_{k-1})$

$S_k \in S = \{S_1, S_2, \ldots, S_m\}, 1 \leq k \leq n$

5. Optimization solution

5.1. Determination of the feasible tool set

Based on the internal geometry of the pocket, the smallest tool size $D(T)$ for pocket machining equals to the minimum distance between a convex vertex and another one. The largest tool size $D(T)$ can be obtained from the maximum offset distance without gouging. The critical tool $T_{cri}$ and the efficient tool $T_{eff}$ are the smallest feasible tool and the largest feasible tool respectively.

Generally, the diameter of the critical tool $D(T_{cri})$ and the efficient tool $D(T_{eff})$ are equal to $D(T)$ and $D(T)$ respectively. But in fact, there are not always the tools whose diameters are same as $D(T)$ and $D(T)$. Hence, a method to select the critical tool $T_{cri}$ and efficient tool $T_{eff}$ is proposed in this paper.

Given $X$ cutting tools(1,2,…,$X$) with the diameter in descending order, the critical tool $T_{cri}$ and efficient tool $T_{eff}$ are
then selected by the following Eq.(22) and Eq.(23)

\[ T_{cri} = \{ T_i : \exists D(T_i) = D(T_j), \forall i \neq j, X \} \quad (22) \]

\[ T_{cri} = \{ T_i : \exists D(T_i) < D(T_j), \forall i \neq j, X \} \quad (23) \]

Thus the feasible tool set can be expressed as

\[ T_f = \{ D(T_i) \leq D(T_j) \leq D(T_k) \} \quad (24) \]

5.2. Identification of the accessible area

In the 2.5D pocket milling process, it is imperative to identify the accessible area of each feasible tool. In this paper, the Contour offset approach [13] proposed by D’Souza et al. is adopted.

5.3. Graph algorithm

As shown in Fig.1, an example of the graph that represents all feasible tool sequences with 5 tools is given. In which the node represents the shape of the pocket after \( t_i \) is done machining. Fig.1, 16 feasible tool sequences can be obtained by the 15 node pairs. The edge represents the energy consumption and machining cost. For instance, edge (3,4) is the energy consumption and machining cost for \( t_4 \) after \( t_3 \) is done. The optimal tool sequence is the minimum energy consumption and machining cost from the start node to the final node which can be obtained using Dijkstra algorithm [14].

6. Case study

To validate the proposed model and optimization approach, a case study on machining a 2.5D pocket, as shown in Fig.2, is conducted. The machining experiments are performed on a PL700 vertical machining centre. During the experiment, 15 cutting tools are available in the workshop with the diameters [2,4,5,6,8,10,14,16,18,20,28,32,36,40,45]. The critical tool \( D(T_{cri})=6\text{mm} \) and the efficient tool \( D(T_{eff})=20\text{mm} \) are identified according to Eq.(22) and Eq.(23). After that, the feasible tool set \( T_f \) is obtained through Eq.(24). The total stock of roughing and finishing are 6.0mm and 0.12mm respectively. Meanwhile, in order to ensure the machining accuracy and surface quality of the production, the critical tool \( T_{cri} \) is only one feasible cutter who is adopted in finishing operation. Before the machining, as shown in Table1, the number of machining passes and cutting parameters of each feasible cutting tool are obtained according the work in [22]. In Table2 and Table3, the machining cost and the coefficients in the relevant equations are listed.

6.1. Optimization results

As shown in Table 4, the optimization results of Minimum energy \( E_{total} \), Minimum cost \( C_{total} \), and Minimum \( E_{total} \& C_{total} \) are obtained respectively. The calculated machining time \( T_M \) is also listed in Table 4. Moreover, the energy consumption for 6 tool sequences with only the critical tool and a larger feasible tool are shown in Table 5.

6.2. Results analysis and discussion
From the optimization results in Table 4, it can be concluded that milling using a tool sequence with multi-tools shows significant advantages in reducing energy consumption and machining cost compared to single-tool sequence with the only critical tool. For instance, compared to single-tool sequence \( (T_1) \), the milling strategy with the tool sequence \( (T_1,T_2,T_3) \) reduces the energy consumption and machining cost by 30.6% and 22.8% respectively.

When the optimization is to minimize energy consumption and machining cost, the milling strategy with the tool sequence \( (T_2,T_3,T_4) \) strikes a balance between the energy consumption and machining cost. Compared to the milling strategy to minimize energy consumption, it increases energy consumption by 11.5% but decreases machining cost by 10.3%. Similarly, compared to the milling strategy to minimize machining cost, it increases the machining cost by 1.4% but decreases the energy consumption by 3.3%. In addition, when compared to the empirical milling strategy, the energy consumption and machining can be reduced by 11.3% and 12.2% respectively.

The cutting tools in optimal tool sequence should not be too much. The reason is that every tool change incurs a machining time and energy consumption penalty due to the rapid-feed movement and slowly-approach motion without material removal of cutters.

The tool sequence which has shorter machining time also shows a decreasing trend in energy consumption. This is because in such kind of machine tools whose fixed power \( P_0 \) accounts for a large proportion of the total input power \( P_{total} \), reducing the machining time means saving energy.

As shown in Table 5, energy consumption for 6 tool sequences with only the critical tool and a larger feasible tool are given. The energy consumption firstly decreases with the increase of the larger feasible tool diameter, and then increases. This is because that a larger feasible tool can quickly remove the workpiece material and reduce the machining time. Hence the total energy consumption can be reduced as the fixed energy is time dependent and takes a big advantage of larger cutters' high machining efficiency cannot be considered blindly when choose cutting tools.

7. Conclusion

In this paper, the influence of tool sequence on energy consumption of 2.5D pocket CNC milling is firstly analyzed. And a multi-objective tool sequence optimization model for minimizing energy consumption and machining cost is proposed and solved by the graph algorithm. Finally, a case study is conducted to validate the proposed model and approach and find the trade-off solutions between energy consumption and machining cost. Based on the work presented in this paper, manufacturers can easily select the optimal tool sequence to reduce energy and save cost in 2.5D pocket CNC milling process. Further study of tool sequence optimization for freeform surface milling considering energy consumption will be our future research.
