ABSTRACT

INTRODUCTION

- Reducing 30-day hospital readmissions is a top healthcare priority. However, there is little research describing the risk factors of readmission among patients with diabetes, especially for older adults. Understanding what the risk factors are for 30-day hospital readmission for older adults with type 2 diabetes (T2DM) would help identify patients at risk of rehospitalization.
- Objective: The aim of this study was to identify factors associated with 30-day unplanned hospital readmissions among older adults with T2DM. Factors to be investigated are: patient demographics, whether patients were at risk for falling, and patients' activities of daily living (ADL) at discharge.
- Methods: Participants were older adults > 65 years old with T2DM, admitted to a community hospital from January 2012-January 2017. Of 843 patients, 200 were randomly selected to have their electronic medical records reviewed for this study.
- Results: Patients readmitted within 30 days of discharge were similar to patients who were not readmitted on most demographic characteristics, except for hospitalization in the 12 months before admission. No statistically significant differences were found between readmitted and not readmitted patients on whether they were at risk for falls or their ADLs at discharge.
- Conclusion: Older adults with T2DM who were readmitted within 30 days post-discharge were more likely to have had a previous hospitalization. Readmitted patients did not differ from not readmitted patients on risk for falls or ADLs at discharge. Future analyses will incorporate additional potential predictors of unplanned hospital readmissions.

METHODS

- PARTICIPANTS
  - Inclusion Criteria: Participants were older adults > 65 years old admitted to a community hospital from January 1, 2012 to January 1, 2017 with a diagnosis of T2DM at their index hospitalization, defined as patients' first hospitalization to occur during the study period.
  - Exclusion Criteria: Patients were excluded if they died during the index hospitalization or were discharged to hospice.

- PROCEDURES
  - Of the 843 patients who met the study's inclusion criteria, 200 were randomly selected to have their electronic medical records reviewed.
  - Factors investigated were: patients' demographics and whether patients were hospitalized for cardiovascular disease.

RESULTS

- Readmission Rate: Of the 200 patients, 15.5% (N=31) had an unplanned hospital readmission within 30 days of discharge.
- Data on demographic characteristics are presented in Table 1.

</tbody>
</table>

In general, there were no statistically significant differences between patients who were readmitted and patients who were not readmitted on demographic characteristics.

No statistically significant difference was found between readmitted and not readmitted patients on whether they were at risk for falls or their ADLs at discharge.

CONCLUSIONS

- Readmitted and not readmitted patients with T2DM were similar on most demographic characteristics.
- Patients who had been readmitted within 30 days of discharged were more likely than patients who had not been readmitted to have had a previous hospitalization in the 12 months prior to admission.
- No differences were found between readmitted and not readmitted patients on their risk for falls or their ADLs at discharge.
- Future analyses of these data will incorporate other potential predictors of hospital readmission in this population.
