ABSTRACT Eukaryotic cells, when faced with unfavorable environmental conditions, mount either pro-survival or pro-death programs. The conserved cyclin C-Cdk8 kinase plays a key role in this decision. Both are members of the Cdk8 kinase module that, along with Med12 and Med13, associate with the core Mediator complex of RNA polymerase II. In *Saccharomyces cerevisiae*, oxidative stress triggers Med13 destruction, which releases cyclin C into the cytoplasm to promote mitochondrial fission and programmed cell death. The SCF *Grr1* ubiquitin ligase mediates Med13 degradation dependent on the cell wall integrity pathway, MAPK Slt2. Here we show that the AMP kinase Snf1 activates a second SCF *Grr1* responsive degron in Med13. Deletion of Snf1 resulted in nuclear retention of cyclin C and failure to induce mitochondrial fragmentation. This degron was able to confer oxidative-stress-induced destruction when fused to a heterologous protein in a Snf1 dependent manner. Although snf1Δ mutants failed to destroy Med13, deleting the degron did not prevent destruction. These results indicate that the control of Med13 degradation following H₂O₂ stress is complex, being controlled simultaneously by CWI and MAPK pathways.

INTRODUCTION

All eukaryotic cells are continually exposed to changing environmental conditions. Consequently, they have evolved elaborate mechanisms to both sense damage and transmit this signal to the nucleus. The resulting response varies dependent upon the stress encountered but in gross terms cells have to decide whether to activate pro-survival or pro-death programs. Despite this being a critical decision point, what remains understudied are the molecular details of how cells decide their fate upon encountering unfavorable environments. Previous studies revealed that the conserved cyclin C protein plays a key role in this decision in response to increased environmental reactive oxygen species (ROS) [1-9]. Cyclin C, together with its kinase partner Cdk8, Med12 and Med13, form the Cdk8 Kinase Module (CKM) of the multi-subunit Mediator complex. This complex acts as an interface between DNA bound transcription factors and RNA polymerase II (RNAP-II [10-12]). When the CKM module is bound, it predominantly negatively regulates expression of a subset of stress response genes [1, 13-16]. Following an increase in environmental ROS (induced by H₂O₂ treatment), this repression is relieved by the nuclear release of cyclin C to the cytoplasm [4, 7, 8]. Intriguingly, here cyclin C plays a second role directing stress-induced mitochondrial fission as well as promoting programmed cell death (PCD) [7, 8]. Consistent with...
this function, cells lacking cyclin C are less able to execute stress-induced mitochondria fission and are more resistant to oxidative stress [3, 7]. Taken together, these results argue that cyclin C nuclear release must be carefully controlled as it signals a commitment to PCD.

Our previous studies have revealed that a complex molecular mechanism controls cyclin C nuclear release. In response to environmental ROS, cyclin C is directly phosphorylated by Slt2, the MAP kinase of the Cell Wall Integrity (CWI) signal transduction pathway ([6] and Fig. 1A). This canonical pathway is characterized by a family of cell-surface sensors (Wsc1, Mid2 and Mtl1 [17]) that transmit the stress to a small G protein Rho1, which thereafter activates protein kinase C (Pkc1 [18, 19]). Once activated, Pkc1 transmits the intracellular signal to the MAPK Slt2/Mpk1 [20] as well as to the pseudo-kinase Kdx1/Mip1 via the MAPK module [21]. In addition to cyclin C [6], Slt2 directly phosphorylates two other transcription factors (Rlm1, Swi4/Swi6) that stimulate the expression of other stress response genes [21-24].

More recently, Slt2 has also been shown to regulate gene expression by phosphorylating tyrosine-1 of the RNAP II carboxy-terminal domain [25]. This event is associated with pause/termination processes in mammals [26]. Intriguingly, it is required for the loss of cyclin C and Cdk8 from target genes following stress in yeast [25].

In S. cerevisiae, Med13 destruction is required for cyclin C nuclear release [27]. Consistent with this, cyclin C is cytoplasmic in unstressed med13∆ and the mitochondria are predominantly fragmented [27]. More recently we identified SCF^{Grr1} as the E3 ligase that mediates Med13 destruction [9]. Like other SCF targets [28], recognition of this phospho-degron requires it first to be primed by one kinase (cyclin C-Cdk8) and then activated by another (Slt2). These studies also revealed that phosphorylation of cyclin C by Slt2 is required for the SCF^{Grr1} to recognize Med13 [9] (Fig. 1A). Like the Slt2-degron, this domain lies within the large intrinsic disordered region (IDR) of Med13 [Fig. 2A]. IDR’s are defined by a continuous stretch of disordered promoting residues which can easily transition into more ordered states. These structural transitions afford IDR’s great flexibility and as such these regions are known to play key roles in macro-molecular decisions especially those that influence signaling pathways [29, 30].

In addition to Slt2, the highly conserved 5’ adenosine monophosphate-activated protein kinase (AMPK), which plays a major role in the utilization of alternative carbon sources after glucose depletion [32], is also activated in response to various environmental stresses including oxidative stress [33]. In S. cerevisiae, the catalytic subunit of the heterotrimeric AMPK complex is encoded by SNF1. Other members of the complex (outlined in Fig. 1B) include two regulatory subunits, the γ subunit Snf4 and one of the.

**FIGURE 1:** (A) Cdk8 module regulation by the CWI MAPK pathway. H2O2 stimulates cell wall sensors Wsc1, Mtl1 and Mid2, leading to activation of Rho1 that in turn triggers the cell wall integrity (CWI) MAPK pathway by activating Protein Kinase C (Pkc1). Activation of this cascade triggers the MAPK, Slt2, to directly phosphorylate cyclin C, an event required for the 1st step towards its release from the nucleus. The second step requires Slt2 to directly phosphorylate Med13-degron^{742-844}, which targets it for ubiquitin mediated degradation by SCF^{Grr1}. Cyclin C-Cdk8 activity is needed to prime the degron before it is recognized by SCF^{Grr1} [9]. (B) Outline of the AMPK pathway in yeast. It remains unknown how this pathway is activated in response to H2O2 stress. The gray box represents the Snf1 kinase complex (see text for details).
three alternative β subunits, Sip1, Sip2, or Gal83 [32]. The three β isoforms determine the respective cellular addresses after activation of Snf1, with the Snf1-Gal83 isoform being enriched in the nucleus [34-36]. The catalytic activity of Snf1 is regulated by phosphorylation at Thr-210, which is located in the activation loop of its kinase domain [37]. This is executed by one of three upstream kinases, Sak1, Tos3, or Elm1 [33, 38, 39]. These, in turn, are activated by an unknown mechanism in response to a variety of stresses, which lends specificity to the system [33].

In this report we show that Snf1, Sak1 and at least one β isoform are required for the H$_2$O$_2$ induced degradation of Med13. Using yeast two-hybrid analysis, the Snf1-interacting domain on Med13 was identified. This domain lies in the large IDR of Med13 and is recognized by SCF$_{Grr1}$ after Snf1 directed phosphorylation. Consistent with this, Snf1 is required for efficient cyclin C nuclear release following H$_2$O$_2$ stress. Taken together, this reveals that Med13 degradation is regulated by two SCF$_{Grr1}$ degrons that are regulated by three different classes of kinases, a Cdk, a MAPK and an AMPK. As all three kinases are required for Med13 degradation, this complex molecular mechanism ensures that cyclin C nuclear release is tightly controlled and prevents its untimely release into the cytoplasm.

RESULTS

Med13 contains two SCF$_{Grr1}$ phosho-degrons

We have previously shown that SCF$_{Grr1}$ is the E3 ligase responsible for mediating Med13 degradation following H$_2$O$_2$ stress [9]. This degron (amino acids 742-844, Fig. 2A,) is primed by cyclin C-Cdk8 and activated by Slt2. In these studies we also observed that another Med13 domain (amino acids 571-650) can also bind to Grr1 using the Gal4 yeast two hybrid (Y2H) assay [40]. These results were repeated using two baits, wild-type Grr1 and a grr1ΔFΔL mutant, which can neither bind to the SCF or recognize substrates [41, 42]. As anticipated, the Gal4 activating domain Med13[571-650] fusion protein (hereon out referred to as degron[571-650]) can associate with wild-type Grr1 as an interaction is detected selecting for the dual HIS3 and ADE2 reporter genes (Fig. 2B). The vector control and mutant bait were unable to grow on this media suggesting that the interaction is specific. To confirm that degron[571-650] is responsive to SCF$_{Grr1}$ we examined its degradation, by Western blot analysis, following 0.4 mM H$_2$O$_2$ treatment in wild-type and grr1Δ cells. This concentration of H$_2$O$_2$ induces mitochondrial outer membrane permeabilization (MOMP) dependent regulated cell death response in yeast [43-45] and triggers cyclin C nuclear release [4, 6, 7, 27]. The results show that although less degron[571-650] is present in unstressed grr1Δ cells, the protein is more stable following H$_2$O$_2$ stress (Fig. 2C and quantified in 2D). Taken together with the Y2H data, these results argue that degron[571-650] is a SCF$_{Grr1}$ responsive degron. They are also consistent with our previous published work demonstrating that Grr1 is required for H$_2$O$_2$ induced degradation of Med13 [9].

Snf1 is required for stress-induced degradation of Med13

We next addressed if the H$_2$O$_2$ mediated destruction of degron[571-650] required Cdk8 kinase activity. To execute this, the degradation of degron[571-650] was monitored as de-
scribed above, in cells deleted for cyclin C harboring either functional myc-tagged cyclin C or a vector control. The results revealed that degron571-650 is degraded with the same kinetics in the presence or absence of cyclin C (Fig. S1A and quantified in Fig. S1B). These results suggest that another kinase phosphorylates degron571-650. One candidate is the PAS kinase. This kinase is required for glucose homeostasis, and is encoded by two orthologs Psk1 and Psk2 [46]. Intriguingly, previous Y2H studies have revealed that a domain of Med13 (amino acids 505-703), that encompasses degron571-650, interacts with Psk1 [47]. The Y2H assay was repeated using Psk1 as bait and the smaller degron571-650 as prey and again an interaction was observed (Fig. S2A). We next tested if the PAS kinase plays a role in the degradation of full length Med13. Wild-type and psk1Δ psk2Δ cells harboring a functional HA-tagged Med13 plasmid [9] were treated with H2O2 and Med13 degradation was monitored by Western blot analysis. The results show that Med13 is degraded with similar kinetics in the mutant and wild-type cells (Fig. S2B and quantified in Fig. S2C). These results indicate that although the PAS kinase can interact with degron571-650, it is not required for Med13 degradation following H2O2 stress.

Snf1 has been identified as the AMPK kinase that is activated in response to oxidative stress [33]. Therefore, we next addressed if Sak1 is required for H2O2 induced Med13 degradation. The degradation assays described above were repeated in sak1Δ cells and results revealed that Med13 was again significantly more stable in sak1Δ than wild-type cells (Fig. 3A and quantified in Fig. 3C). This result supports

![FIGURE 3: Snf1, Sak1 and at least one β subunit are required for degradation of Med13 following H2O2 stress. (A) Wild-type (RSY10), snf1Δ (RSY2080), sak1Δ (YP0ah17) and gal83Δ sip1Δ sip2Δ (MSY557) cells harboring full length Med13-HA (pKC801) were treated with 0.4 mM H2O2 for the timepoints indicated and Med13-HA levels analyzed by Western blot. Tub1 levels were used as a loading control. (B) snf1Δ cells harboring Med13-HA (pKC803) and either wild-type Snf1 (JG1193), a vector control (pRS316) or snf1K84R (JG1338) were treated and analyzed as described in (A). the previously proposed model that Sak1 is the AMPKK that activates Snf1 in response to oxidative stress [33]. We next addressed if the nuclear enriched isoform, Snf1-Gal83, [34-36, 52], is required for Med13 degradation under similar circumstances. Unexpectedly, the results show that Med13 is still degraded in gal83Δ cells (Fig. S3A). Likewise, similar results were obtained when Med13 degradation was monitored in a sip1Δ sip2Δ strain (Fig. S3A). However, deletion of all three β subunits significantly inhibited the degradation of Med13 to a similar extend as observed in snf1Δ (Fig. 3A and quantified in Fig. 3C). Taken together, this suggests at least one of the β subunits of the Snf1 complex is required for Med13 degradation following H$_2$O$_2$ stress.

Snf1 activation alone is not sufficient to mediate Med13 degradation

We next addressed if Snf1 activation was sufficient to mediate Med13 degradation in the absence of H$_2$O$_2$ stress. To execute this Med13 levels were examined in wild-type cells after they had been switched from 2% to 0.05% glucose which, is sufficient to activate Snf1 (Fig. 4A and [33]). No differences in Med13 levels were observed following glucose deprivation (Fig. 4B). Taken with the results presented in Fig. 3, this suggests that Snf1 activation is necessary but not sufficient to mediate the degradation of Med13 following H$_2$O$_2$ treatment.

The CWI pathway sensors proteins are not required for Snf1 activation

It is known that both the CWI and AMPK pathways are activated in response to oxidative stress, but how these two pathways communicate is not well understood [53]. Importantly, although it is known how the signal is transmitted to the CWI pathway, it is unclear how the AMPK pathway is activated (Fig. 1B). One possibility is that the pathways crosstalk through the cell wall sensor proteins. To test this, we examined Snf1 phosphorylation status in a strain lacking the three cell wall sensors (Wsc1, Mid2 and Mtl1, [17]). Consistent with previously published work [33], Snf1 is phosphorylated following H$_2$O$_2$ treatment in a Sak1 dependent manner (Fig. 4C). Likewise the cell wall sensor triple mutant is also able to activate Snf1 following H$_2$O$_2$ treatment (Fig. 4C). These results suggest that the activation of the CWI pathway is not required to transmit the stress signal to the AMPK pathway. Others have demonstrated that Snf1 is not required for activation of Slt2 [54]. Consistent with this, we observed that the Med13 degron $^{571-650}$ is still degraded following H$_2$O$_2$ stress when a mutant of cyclin C, that cannot be phosphorylated by Slt2 (S266A, [6]), is used as the sole source of cyclin C (Fig. S1C and D). Taken together, these results argue that the AMPK and MAPK signaling pathways act independently of each other. The extension of this conclusion is that both pathways contribute independently to regulating Med13 destruction following H$_2$O$_2$ stress.

FIGURE 4: Snf1 activation does not mediate Med13 degradation. 

(A) Mid-log -type cells (RSY10) growing in 2% glucose (T=0) were switched to media containing 0.05% glucose. Snf1 phosphorylation and Snf1 itself were detected as described in materials and methods for the timepoint indicate. 

(B) Wild-type cells harboring Med13-HA (pXCB01) were switched to media containing 0.05% glucose. Med13-HA levels were detected by Western blot analysis for the timepoints indicated. Tub1 was used as a loading control.

(C) As in (A) except that Snf1 phosphorylation was monitored after 0.4 mM H$_2$O$_2$ treatment in the strains indicated.

The Snf1 degron lies within the IDR of Med13

Snf1 has previously been shown to phosphorylate a SCF$^{Sak1}$ fusion protein (degron $^{571-650}$) is a Snf1 responsive degron by monitoring its H$_2$O$_2$ mediated degradation in snf1Δ cells. The results show that degron $^{571-650}$ is more stable in snf1Δ cells compared to wild type following H$_2$O$_2$ stress (Fig. 5A and quantified in Fig. 5B). This suggests that degron $^{571-650}$ is a Snf1 responsive degron. To further support this conclusion, we examined the degradation kinetics of a degron mutated for either of the potential Snf1 phosphorylation sites previously identified in proteomic screens (S587 [56] and S636 [57], Fig.6A), although none of these sites perfectly fit the Snf1 consensus sequence [58, 59]. The studies revealed that both mutants were degraded following H$_2$O$_2$ treatment with kinetics similar to wild type (Fig. S3B). We also noted that serine 634 could potentially be phosphorylated by Snf1 (see Fig. 6A). As it lies very close to serine 636, we made a double mutant (S634A, S636A) and repeated the assay. Again this mutant degron was degraded following H$_2$O$_2$ treatment (Fig. S3B). However, the triple mutant (S587A, S634A, S636A) exhibited enhanced stability following H$_2$O$_2$ stress (Fig. 5C and quantitated in Fig. 5B). Taken together, these results suggest that Snf1 phosphorylates Med13 following H$_2$O$_2$ stress targeting S587, S634 and S636. Consistent with this
model, we (Fig. 5D and S3C) and others [60] have shown that Snf1 can co-immunoprecipitate with Cdk8 both before and after H$_2$O$_2$ stress. As cyclin C directly binds to the adjacent degron $571-650$ (Fig. 2A and [9]), this places Snf1 in close proximity to degron $571-650$. In addition, these data also support the notion suggested by others, that a subpopulation of Snf1 is nuclear in unstressed cells [34, 52, 60].

To address if Snf1 directly phosphorylates Med13, kinase assays were performed with wild-type and kinase dead Snf1 (K84R). The activated kinase was immunoprecipitated from yeast protein extracts prepared from either wild type (left panel) or cdk8$\Delta$ cells (right panel) and Med13-degron $571-650$ (GST-Med13$571-906$, S608A purified from E. coli) as the substrate. The reactions were separated by SDS PAGE and subject to autoradiography. Lower panels: Coo massie stained gels showing the input used in the kinase assays.
not phosphorylate GST, so this control was not included here [62]. The results (Fig. 5F) show that Snf1 is able to directly phosphorylate degron571-650. However, despite taking the precautions listed above, kinase activity was also observed using the kinase dead version. This suggests that another kinase that immunoprecipitates with Snf1 is able to phosphorylate this degron. One strong possibility is Cdk8, which is a proline directed kinase that can phosphorylate the minimal consensus sequence S/T-P [63]. Degron571-650 contains one such site (Fig. 5E). Therefore the kinase assays were repeated using Snf1 extracts isolated from a cdk8Δ strain. The results show that degron571-650 was phosphorylated by Snf1 and this activity was reduced in the kinase dead control (Fig. 5F). Taken together, these results are suggestive that Snf1 directly phosphorylates Med13571-650. However, as some phosphorylation of degron571-650 was observed when Snf1K84R was used, we cannot rule out the possibility that an intermediary kinase may be playing a role.

**Other potential Snf1 sites on Med13 are not needed for its degradation following H2O2 stress**

The Snf1 proteomic screen mentioned above also identified five additional potential Snf1 sites in Med13 [57]. Intriguingly, these sites all lie within the large IDR of Med13 (Fig. 6A). As IDR’s provide ideal environments for post-translational modifications, which effect signaling events [64], we asked if these additional sites also play a role in Med13 degradation. To address this question, Med13-HA fragments were fused to the SV40 nuclear localization sequence (NLS) and assayed for H2O2 mediated destruction. The results revealed that the construct that contains both degrons as well as all the potential Snf1 sites (amino acids 306-906) is degraded. However, the Med13306-570 construct, that contains the remaining potential Snf1 sites but not the two MCFp571-650 responsive degrons, was significantly more stable (Fig. 6B). This suggests that these other potential Snf1 sites do not play a role in the H2O2-stress mediated degradation of Med13. To address if the head and tail regions of Med13 contain unidentified Snf1 sites, Med13 constructs spanning these regions (amino acids 1-306 and 907-1420) were also tested, as described above, for stability following H2O2 stress. The results (Fig. 6C) demonstrate that these constructs are not destroyed under these conditions. This supports our conclusion that the Snf1 degron lies within amino acids 571-650. Degron742-844 also contains a potential Snf1 target site (Fig. 6A). However, this degron, when fused to the Gal4 activating domain, is destroyed following H2O2 stress in wild-type and snf1Δ cells alike (Fig. 6D). Taken together, these results support the above conclusions that the Snf1 phosphorylation sites lie within degron571-650.

**Snf1 is necessary for cyclin C nuclear release and stress-induced mitochondrial fission**

As Med13 degradation is required for cyclin C nuclear release [9, 27], we next tested if Snf1 was also required for this event. To address this, the location of a functional cyclin C-YFP reporter protein [5] before and after stress in wild-type and snf1Δ cells was examined (Fig. 7A and quantified in 7B). The results show that a majority of cyclin C-YFP is cytoplasmic in wild-type cells, whereas it remains significantly more nuclear in snf1Δ cells (Fig. 7A and quantified in 7B). These data indicate that Snf1 is required for the oxidative stress induced nuclear release of cyclin C. As cyclin C nuclear release initiates stress-induced mitochondrial fission [4, 7, 8], mitochondrial morphology in snf1Δ cells was examined. As previously reported, unstimulated wild-type cells exhibited mainly reticular mitochondrial mor-
Snf1 mediated degradation of Med13

Med13-degron571-650 is not required for the degradation of Med13 following H$_2$O$_2$ stress

We next addressed if Snf1 mediated phosphorylation of Med13 is required for Med13 degradation. Degron571-650 was deleted from full length Med13 and the degradation kinetics of this construct (Med13571-650) was examined in med13Δ cells. The results show that Med13571-650 was degraded with kinetics similar to wild type (Fig. 8A, upper two panels, quantified in Fig. 8B). We also observed that this construct retained cyclin C in the nucleus in unstressed cells and released it into the cytoplasm following H$_2$O$_2$ stress (Fig. S5). These results were unexpected as deletion or inactivation of Snf1 results in Med13 stabilization following H$_2$O$_2$ stress [9]. These results suggest a complex model in...
which the function of either Snf1 or Slt2 is only required when their respective degron is present. If correct such a model would predict that the degron impeaches degradation when not phosphorylated. Moreover, these studies predict independent roles for these two signaling pathways that ultimately direct in the same outcome of Med13 degradation.

**DISCUSSION**

Our previous work has shown that nuclear release of the yeast and mammalian cyclin C predisposes cells to initiate PCD following stress [7, 8]. In S. cerevisiae, this nuclear release requires the destruction of Med13 [27], mediated by the E3 ligase complex SCF<sub>Grr1</sub>, which requires Slt2 and Cdk8 activity [9]. In this current work, we provide evidence that Sak1 activated Snf1 is also required for H<sub>2</sub>O<sub>2</sub> induced Med13 degradation and cyclin C nuclear release. In the absence of this kinase, Med13 degradation following H<sub>2</sub>O<sub>2</sub> stress is inhibited and cyclin C remains predominantly nuclear. Consistent with this model, we showed that Snf1 is required for the degradation of the degron<sub>571-650</sub>. Paradoxically, deletion of this degron did not prevent H<sub>2</sub>O<sub>2</sub> induced destruction of Med13. Instead, this mutant exhibited H<sub>2</sub>O<sub>2</sub> induced Med13 degradation and cyclin C nuclear release. Intriguingly, deletion of the Slt2-responsive degron (Med13<sub>742-844</sub>) also did not protect Med13 from H<sub>2</sub>O<sub>2</sub> induced degradation, although the protein was slightly more stable than wild type. Taken together, this study indicates that Slt2 and Snf1 pathways cooperate to trigger Med13 destruction. The use of two required pathways may help insure the proper signals are in place to target Med13.

To accommodate these two results, the following model that best fits the data is proposed (outlined in Fig. 8C). In unstressed cells the IDR of Med13, which encompasses both degrons, is protected from SCF<sub>Grr1</sub> activity (depicted by red circle in Fig. 8C) by an unknown mechanism. Following H<sub>2</sub>O<sub>2</sub> stress two events happen, the hierarchy of which is unknown. The protection is lost (depicted by green circle in Fig. 8C) and activated Snf1 and Slt2 phosphorylate their respective degrons, triggering SCF<sub>Grr1</sub> mediated degradation of Med13. Although we currently favor the hypothesis that Snf1 directly phosphorylates Med13, we could not definitively exclude the possibility that Snf1 may promote Med13 phosphorylation indirectly via an intermediary kinase. That being said, the model presented in Fig. 8C could accommodate this possibility. More importantly however, the model supports the observation that both the AMPK and MAPK pathways act independently of each other (Fig. 4), and are required for Med13 degradation. However, in the absence of either the Snf1 or Slt2 degron, this protection is lost, allowing SCF<sub>Grr1</sub> to recognize either activated degron. This model also accounts for the observation that when either degron is expressed in isolation, it requires its respective kinase to render it recognizable by SCF<sub>Grr1</sub>.

If this model is correct, then how could this region be protected from AMPK and MAPK activity in unstressed cells? One strong possibility could be connected to the fact that both degrons lie within the very large IDR of Med13 (Fig. 2A). IDR’s are known to endow proteins with highly

**FIGURE 8:** Either Med13 degron is sufficient for Med13 degradation. Values represent averages ± SD from a total of at least two Western blots from independent experiments. For clarity, the degradation kinetics of wild-type Med13-HA from previous experiments was included. (C) Model depicting how two SCF<sub>Grr1</sub> phosho-degrons mediate the destruction of Med13 following H<sub>2</sub>O<sub>2</sub> stress. In unstressed cells cyclin C-Cdk8 phosphorylates degrons<sub>742-844</sub> [9] but both degrons are protected by an unknown mechanism from Snf1 and Slt2 kinase activity (depicted by the red circle). Following H<sub>2</sub>O<sub>2</sub> stress Snf1 and Slt2 are activated and permitted access to the now exposed degrons. This results in SCF<sub>Grr1</sub> mediated degradation of Med13 and cyclin C nuclear release (not shown).
malleable structures that undergo disorder-to-order transitions [65]. It has also been proposed that IDR’s can have different binding partners that transiently associate [66]. In some cases, this can lead to proteins binding the same region that possess unrelated, or even opposite functions [67]. Thus, proteins that contain IDR’s are frequently involved in signaling as they can easily change their conformational state in response to changing environmental conditions. Taken together, it is feasible to propose that in environmental state in response to changing environmental conditions. Upon stress, the confirmation changes and the degron becomes exposed. This model is also consistent with the observation that IDR’s are notorious for being regulated by multiple kinases [64, 68]. This has led to the idea that IDR’s and multiple phosphorylation events together provide structural variability [69], resulting in ultra-sensitive molecular switches that are triggered at a threshold level of phosphorylation. Thus, our results suggest a model in which Med13 degradation is regulated by three types of different kinases, a cyclin dependent kinase, a MAP kinase, and an AMPK.

Lastly, here we show that Snf1 phosphorylates Med13, either directly or by an intermediary kinase, as well as associating with the CKM before stress (Fig. 5D). These results are consistent with a growing number of papers that have shown that a sub-population of the Snf1-Gal3 isofrom is present in the nucleus under normal conditions [52, 60, 70], as well as enriched in the nucleus upon glucose starvation [34-36]. In addition, Sak1 is needed for Snf1 nuclear localization [71]. In support of this model, Snf1, Gal83 and Sak1 localize to the SUC2 promoter under non-starvation conditions [52]. This promoter is also negatively regulated by the CKM [72]. Repression is relieved by Snf1 mediated phosphorylation of two proteins known to repress SUC2 expression, the DNA binding protein Mig1 [73] and the glucose kinase Hxk2 [52, 74], causing them to be released into the cytoplasm [75, 76]. Likewise, carbon starvation results in the degradation of cyclin C [2], one event that occurs in the cytoplasm [4]. Surprisingly, we found that although Sak1 is needed for Med13 destruction following H2O2 stress, deletion of Gal83 has no effect (Fig. 3A and S2A). However, deletion of all three β-subunits does inhibit Med13 degradation. This would suggest that in the absence of Gal83, either Sip1 or Sip2 are able to activate nuclear Snf1. However, the Snf1-Sip1 and Snf1-Sip2 isoforms have not been reported to be nuclear, dispersing either to the vacuolar membrane (Sip1) or remaining cytoplasmic following carbon deprivation (Sip2) [34-36, 77]. Further studies need to be executed to address if Sip1 or Sip2 can translocate into the nucleus in the absence of Gal83. Interestingly, just recently the Mitochondrial Voltage-Dependent Anion Channel Protein Por1 (yVDAC1) has been shown to enhance Snf1 nuclear enrichment by promoting the nuclear enrichment of Gal83 [70]. This unexpected finding serves to emphasize that there is still much to learn about the role Snf1 kinase plays in response to changing environmental conditions.

MATERIALS AND METHODS

Yeast strains and plasmids

All strains used in this study are listed in Table S1. Most experiments were performed in the S. cerevisiae W303 strain [78] and are listed in Table S1. Exceptions to this are the sok1Δ (YPDahl17, a gift from S. Hohmann [79]), the sip1Δ sip2Δ (MML1445, a gift from E. Herrero) and psk1Δ psk2Δ strains which are W303-1A strains. The sip1Δ sip2Δ gal83Δ strain (MSY557, a gift from M. Schmidt [80]) is an S288c strain. Finally, the Y2H assays were performed in PJ69-4a [40] that was obtained from the Yeast Resource center, a gift from S. Fields. In accordance with the Mediator nomenclature unification effort [81], we use CNC1 and CDK8 gene designations for cyclin C (SSN8/UME3/SRB11) and Cdk8 (SSN3/UME3/SRB10) respectively. The snf1Δ and gal83Δ strains (RSY1949 and RSY2080 respectively) were constructed using gene replacement methodology as described [82]. The sok1Δ (RSY1976) was a gift from S. Hohmann [79]. All cells were grown at 30°C.

All plasmids used in this study are listed in Table S2. The wild-type epitope tagged plasmids pKC801, pKC803 (MED13-HA), pBK38 (ADH1pro-CNC1-YFP), Snf1-Myc and ADH1pro-CNC1-Myc (pKC337) are functional and have been previously described [1, 4, 5, 9, 83, 84]. All other plasmids were constructed using PCR cloning techniques and details are available upon request. In short, all constructs were amplified from plasmid DNA using Phusion Taq (Thermo), digested using Thermo fast digest restriction enzymes and ligated using Thermo fast ligase into their respective vectors. Site directed mutagenesis (New England Bio-Labs Q5) was used to create plasmids harboring amino acid mutations and the change was confirmed by sequencing (Eurofins Genomics). The MED13 Y2H plasmids were constructed by PCR cloning regions of Med13 in frame with the Gal4 activating domain of pACT2. The NLS-Med13 fusion constructs were made by first creating a backbone vector (pNLS-HA) that contains the SV40 nuclear localization sequence (NLS) in frame with a single HA epitope tag under the control of the ADH1 promoter. PCR-cloning was then used to place fragments of Med13 in frame with NLS. All in frame fusion proteins were verified by sequence analysis. Other plasmids that were used in this study that have been previously described.

Cell growth

Yeast cells were grown in either rich, non-selective medium (YPD) or synthetic minimal medium (SC) allowing plasmid selection as previously described [1]. For all experiments, the cells were grown to mid-log phase (~ 6x10^6 cells/ml) before treatment with low concentrations of 0.4 mM H2O2 as previously described [5]. 25 ml of cells were collected per timepoint, washed in water, then the pellet flash frozen in liquid nitrogen. Yeast two hybrid experiments were executed as described [41]. E. coli cells were grown in LB medium with selective antibiotics. For the kinase assays cells were initially grown in 5D-Ura (1.7 g Yeast Nitrogen Base, 5 g Ammonium Sulfate, 20 g Dextrose per liter), overnight, diluted 1:100-fold into 500 ml of 5D-Ura, and grown for 10–12 h. Thereafter the cells were pelleted, and resuspended in 500 ml 5Gal-Ura (1.7 g Yeast Nitrogen Base, 5 g Ammonium Sulfate, 20 g Galactose per liter)

Western blot analysis and co-immunoprecipitation

Tagged full length Med13-HA constructs were detected by using NaOH lysis of cell pellets exactly as described in [9]. To
detect Med13-HA, 1 in 5000 dilutions of anti-HA antibodies (Abcam) were used. The co-immunoprecipitation analysis was performed essentially as described [85]. Anti-alpha tubulin antibodies (12G10) were obtained from the Developmental Studies Hybridoma Bank, University of Iowa. Western blot signals were detected using either goat anti-mouse or goat anti-rabbit secondary antibodies conjugated to alkaline phosphatase (Sigma) and the CDP-Star chemiluminescence kit (Thermo). Signals were quantitated by CCD camera imaging (Kodak) and standardized to the loading control. All degradation assays were performed two or three times. SEM’s were generated for each point (error bars are indicated on the graphs) and the data analyzed using linear regression analysis using GraphPad Prism 7 program.

**Snf1 activation and kinase assays**

The Snf1 activation assays were executed as follows. Cells were grown to mid-log phase and treated with 0.4 mM H$_2$O$_2$ for the times indicated. They were immediately boiled for 3 minutes and pellets frozen using liquid nitrogen. Protein extracts were made using the NaOH method described in [9] and analyzed by SDS-PAGE and Western blotting. Anti-phospho-Thr172–AMPK (Cell Signaling Technology; Cat. No. 2531) was used to detect phosphorylated Snf1 and polyhistidine antibody H1029 (Sigma-Aldrich) to detect Snf1. This is possible as Snf1 ORF contains 13 contiguous histidine residues at its N terminus.

The *in vitro* kinase assays were executed as follows. Wild-type or cdk8Δ cells harboring either myc-tagged Snf1 or Snf1 kinase dead (K84R) under the control of the GAL1-10 promoter, were first grown in SD-Ura followed by SGal-Ura as described above and then resuspended in lysis buffer (20 mM HEPES, 10 mM KCl, 1 mM EDTA, 1 mM ethylene glycol tetra-acetic acid (EGTA), 50 mM NaCl, 10% glycerol, 1 mM β-mercaptoethanol, Pierce™ Protease Inhibitor Tablets, pH 7.4 with phosphatase inhibitors). Resuspended cultures were lysed using a Microfluidics M-110P homogenizer (Microfluidics) and cell debris removed by centrifugation at 12,000 x g for 30 min. Supernatants were incubated with 5–10 µl of Myc-conjugated magnetic beads (Cell Signaling) for 2–3 h at 4°C. Beads were separated using magnetic force and washed four times with 1 ml of lysis buffer lacking protease inhibitors. Beads containing Myc-tagged proteins were used directly for *in vitro* kinase assays without eluting. GST-Med13 was purified from *E. coli* BL21 DE3 strain as previously described [9] and incubated with the Snf1 immunoprecipitates in 30 µl of reaction buffer containing 1X Snf1 kinase buffer (50 mM Tris-Cl, 10 mM MgCl$_2$, 1 mM dithiothreitol (DTT), pH 7.5, 10 µM ATP, and 7.5 µCi of γ32P-ATP, and reactions were incubated for 35 min at 30°C. Kinase assays were stopped by the addition of SDS–PAGE sample buffer, analyzed by SDS-PAGE, stained with coomassie (30 min), destained for 2 h, dried and exposed to film.

**Fluorescence Microscopy**

Cyclin C-YFP subcellular localization and mitochondrial morphology were monitored as described previously [4, 7]. For all experiments, the cells were grown to mid-log (6x10$^5$ cells/ml), treated with 0.4 mM H$_2$O$_2$ for the timepoints indicated, then analyzed by fluorescence microscopy. Cyclin C-YFP release analysis was performed on cells stained with DAPI in mounting medium (10 mg/ml p-phenylenediamine, 50 ng/ml 4',6-diamidino-2-phenylindole, Molecular Probes) to visualize nuclei and prevent photo bleaching. Images were obtained using a Nikon microscope (model E800) with a 100X objective with 1.2X camera magnification (Plan Fluor Oil, NA 1.3) and a CCD camera (Hamamatsu model C4742). Data were collected using NIS software and processed using Image Pro software. All images of individual cells were optically sectioned (0.2 µM slices at 0.3 µM spacing) deconvolved and the slices were collapsed to visualize the entire fluorescent signal within the cell. Cyclin C-YFP foci were scored as being cytoplasmic when 3 or more foci were observed outside of the nucleus. Mitochondrial fission assays were performed on live cells as described [7]. In brief, mitochondrial fission was scored positive if no reticular mitochondria were observed that transversed half the cell diameter. Fusion was scored when cells exhibited one or more reticular mitochondria the diameter of the cell. Fission and fusion was scored for 200 cells from three independent isolates. Statistical analysis was performed using the Student’s T-test.

**ACKNOWLEDGEMENTS**

We thank. S. Fields, S. Hohmann, E. Herrero, J. Nunnari, M. Schmidt and M. Solomon for strains and plasmids. We thank R. Strich for critical reading of this manuscript. This work was supported by grants from the National Institutes of Health awarded to K.F.C. (GM113196), and J.G (GM100376). The yeast two-hybrid strain was made by work supported by NIH grant P41 RR11823 awarded to T. N. Davis.
